

cfExcelProxy | Methods | setCell

Method name: setCell

Returns: cfExcelProxy

Chainable: yes

Description: Sets a cell's value.

Possible Usages

```
newSheet( row=0, column=1, value="a simple value" )
```

Uses the row and column arguments (0-based index) to assign a value to a cell. In this example, the second column of the first row is set.

```
newSheet( cell="A2", value="another simple value" )
```

Uses the cell argument to assign a value to a cell. This method is much more user-friendly as it makes use of the same coordinates system than in Excel.

```
newSheet( cell="A2", value="last, but not least simple  
value", class="myClass" )
```

Sets a cell's value and applies a class to it. Make sure that the class requested exists by using the `drawClasses()` method or by creating it with `newClass()`.
